What is a Graph

- ◆ A graph consists of a set of vertices(V) and a set of edges(E)
- ◆ $G = (V, E)$
- ◆ V : Vertices (nodes)
- ◆ E : Edges. Each edge is a pair of vertices (v, w)

where $v, w \in V$

- a connection between v and w

5/26/2017 1:00 PM

Graphs

2

What is a Graph

◆ Applications:

■ Airport System

- ◆ Airports are vertices
- ◆ Flights are edges
- ◆ Best path may be shortest flying time or fewest edges (connections)

■ Traffic Flow

- ◆ Intersections are vertices
- ◆ Roads are edges
- ◆ Best path may be fastest time or shortest distance

5/26/2017 1:00 PM

Graphs

3

Graph Terminology

◆ Directed graph (digraph)

- Pair is ordered (u,v) does not imply (v,u)

◆ Undirected graph

- (u,v) is same as (v,u)

5/26/2017 1:00 PM

Graphs

4

Graph Terminology

- ◆ **Weight** - an edge can have a weight (cost)
 - Notation: $w(u,v)$
- ◆ **Path** - a sequence of vertices v_1, v_2, \dots, v_k such that $(v_i, v_{i+1}) \in E$ for $1 \leq i \leq k$
- ◆ **Path length** - the number of edges on the path $(k-1)$
- ◆ There is a **path of length zero** from every vertex to itself, i.e. shortest path.

5/26/2017 1:00 PM

Graphs

5

Graph Terminology

- ◆ **Simple Path**
 - all vertices are **distinct**, except possibly first and last
- ◆ **Cycle (directed graph)**
 - a path of length at least 1 such that $v_1 = v_k$
- ◆ **Cycle (undirected graph)**
 - edges must be distinct
- ◆ **Connected**
 - **undirected** - a path from every vertex to every other vertex
 - **directed**
 - ◆ **Strongly Connected** - direction of edges used
 - ◆ **Weakly Connected** - direction of edges not used

5/26/2017 1:00 PM

Graphs

6

Undirected Graphs

- ◆ **degree of vertex** - # of edges connected to vertex
- ◆ **complete graph (clique)** - all pairs of vertices connected by an edge

5/26/2017 1:00 PM

Graphs

7

Directed Graphs

- ◆ **in-degree** - number of incoming edges
- ◆ **out-degree** - number of outgoing edges

5/26/2017 1:00 PM

Graphs

8

Representation

◆ Adjacency list:

- For each node, list its neighbors on outgoing edges
- Good for sparse graphs
- For weighted graphs, store weight in linked list

◆ Adjacency matrix:

- bit (0,1) matrix to represent presence of edge
- good for dense graphs
- weighted - can store weight in matrix

◆ Tradeoffs

- Adjacency list: space efficient, easy to grow
- Adjacency matrix: fast access, but $O(v^2)$ space

5/26/2017 1:00 PM

Graphs

9

Breadth First Search (BFS)

- ◆ Distance refers to number of vertices in path
- ◆ Visit vertices in increasing order of distance from starting point
- ◆ Use a queue to store vertices "to visit"
- ◆ Not necessarily unique shortest path

5/26/2017 1:00 PM

Graphs

10

BFS(G,s)

```

for each vertex u in V[G] - [s] do
    color[u] = WHITE (White means undiscovered)
    d[u] = Infinity (distance from s)
    pr[u] = NIL (previous vertex)
color[s] = GRAY, d[s] = 0, pr[s] = NIL, Q = {}
ENQUEUE(Q,s)
while Q ≠ {} do
    u = DEQUEUE(Q)
    for each v in Adjacent[u] do
        if color[v] == WHITE then
            color[v] = GRAY (Gray means discovered, but not expanded)
            d[v] = d[u] + 1
            pr[v] = u
            ENQUEUE(Q, v)
    color[u] = BLACK (Black means expanded)
    
```

Depth First Search (DFS)

- ◆ Explores depth first, then neighbors
 - like pre-order, post-order traversal of trees
- ◆ DFS depth not necessarily same as BFS distance
- ◆ Discovers vertices before we visit
- ◆ Use a stack to store vertices "to visit"
- ◆ DFS order not necessarily unique
- ◆ <http://xkcd.com/761/>

DFS(G)

```

for each u in V[G] do
  color[u] = WHITE
  pr[u] = NIL
for each u in V[G] do
  if color[u] == WHITE then
    DFS-VISIT(u)
  
```

DFS-VISIT(u)

```

color[u] = GRAY (discovered u)
for each v in Adjacent[u] do
  if color[v] == WHITE then
    pr[v] = u
    DFS-VISIT(v)
color[u] = BLACK
  
```

Single Source Shortest Path

◆ Given:

- A graph $G = (V, E)$
- A single starting vertex s

◆ Find shortest path to all other vertices

◆ For un-weighted graph use BFS

◆ For weighted graph we have choices

- Dijkstra's Algorithm (positive weights)
- Bellman-Ford Algorithm (negative too)

5/26/2017 1:00 PM

Graphs

15

Applications

◆ Street traffic routing

◆ Plane trip planning

◆ Network packet routing

5/26/2017 1:00 PM

Graphs

16

Naïve solution

- ◆ Enumerate all routes from A to B
- ◆ Add up distances for each route
- ◆ Select shortest
- ◆ Could be millions of possibilities
 - If cycle, then infinite

5/26/2017 1:00 PM

Graphs

17

Dijkstra's Algorithm

- ◆ 50 year old greedy algorithm
- ◆ Idea is to keep distance estimates to neighbors of set S
- ◆ Add neighbor with shortest distance to set S and update other neighbors
- ◆ Doesn't work with negative edges (Bellman-Ford Algorithm does)
- ◆ $O(|E|)$ for dense graphs = $O(|V|^2)$
- ◆ $O(|E| \log |V|)$ for sparse graphs + priorityQ

5/26/2017 1:00 PM

Graphs

18

Initialization

INITIALIZE-SINGLE-SOURCE(G, s)

for each vertex $v \in V[G]$

$d[v] = \text{INFINITY}$ //shortest path estimate

$\text{pr}[v] = \text{NIL}$

$d[s] = 0$

5/26/2017 1:00 PM

Graphs

19

Relaxation

◆ Relaxes the constraint

■ $d[v] = d[u] + w(u, v)$

◆ Relax if edge between u and v gives us an improvement

RELAX(u, v, w) // w is edge weight factor

if $d[v] > d[u] + w(u, v)$ then

$d[v] = d[u] + w(u, v)$

$\text{pr}[v] = u$

5/26/2017 1:00 PM

Graphs

20

Dijkstra's Algorithm

```

DIJKSTRA(G,w,s)
  INITIALIZE-SINGLE-SOURCE(G,s)
  S = {} //set S (cloud)
  Q = V[G]
  while Q ≠ {} do
    u = EXTRACT-MIN(Q)
    INSERT(S,u)
    for each vertex v ∈ Adjacent[u]
      RELAX(u,v,w)
    
```
